# Definition of SSA Form

A program is in SSA form if:

- each variable is assigned a value in **exactly one** statement
- each **use** of a variable is **dominated** by the **definition**

# Advantages of SSA Form

**Makes def-use and use-def chains explicit:**

These chains are foundation of many dataflow optimizations

- We will see some soon!

**Compact, flow-sensitive\* def-use information**

- fewer def-use edges per variable: one per CFG edge

\* Takes the order of statements into account

# Advantages of SSA Form (cont.)

**No anti- and output dependences** on SSA variables

- Direct dependence: **A=1; B=A+1**
  - Antidependence: **A=1; B=A+1; A=2**
  - Output dependence: **A=1; A=2; B=A+1**
- } Cannot reorder

**Explicit merging of values ( $\phi$ ):** key additional information

Can serve as **IR for code transformations** (see LLVM)

# Constructing SSA Form

## Simple algorithm

1. insert  $\phi$ -functions for every variable at every join
2. solve reaching definitions
3. rename each use to the def that reaches it (unique)

## What's wrong with this approach?

1. too many  $\phi$ -functions (precision)
2. too many  $\phi$ -functions (space)
3. too many  $\phi$ -functions (time)

# Where do we place $\varphi$ -functions?

```
V=...; U=...; W=...;
if (...) then {
    V = ...;
    if (...) {
        U = V + 1;
    } else {
        U = V + 2;
    }

    W = U + 1;
}
```

- For V?
- For U?
- For W?

# Where do we place $\phi$ -functions?

```
V=...; U=...; W=...;
if (...) then {
    V1 = ...;
    if (...) {
        U1 = V1 + 1;
    } else {
        U2 = V1 + 2;
    }
}
```

- For V?
- For U?
- For W?

~~V2= $\phi$ (V1, V1); U3= $\phi$ (U1, U2); W1= $\phi$ (W0, W0)~~

W1 = U3 + 1;

}

V3= $\phi$ (V0, V1); U4= $\phi$ (U0, U3); W2= $\phi$ (W0, W1)

# Intuition for SSA Construction

## *Informal Conditions*

If a block  $X$  contains an assignment to a variable  $V$ , then a  $\phi$ -function must be inserted in each block  $Z$  such that:

1. there is a non-empty path between  $X$  and  $Z$ ,
2. there is a path from the entry block (s) to  $Z$  that does not go through  $X$ ,
3.  $Z$  is the first node on the path from  $X$  that satisfies point 2.

# Intuition for SSA Construction

## *Informal Conditions*

If block  $X$  contains an assignment to a variable  $V$ , then a  $\phi$ -function must be inserted in each block  $Z$  such that:

1. there is a non-empty path between  $X$  and  $Z$ , and  
the value of  $V$  computed in  $X$  reaches  $Z$
2. there is a path from the entry block ( $s$ ) to  $Z$  that does not go through  $X$   
there is a path that does not go through  $X$ , so some other value of  $V$  reaches  $Z$  along that path (ignore bugs due to uses of uninitialized variables). So, two values must be merged at  $X$  with a  $\phi$
3.  $Z$  is the first node on the path from  $X$  to  $Z$  that satisfies point 2  
the  $\phi$  for the value coming from  $X$  is placed in  $Z$  and not in some earlier node on the path

# Intuition for SSA Construction

## *Informal Conditions*

### **Iterating the Placement Conditions:**

- After a  $\varphi$  is inserted at  $Z$ , the above process must be repeated for  $Z$  because the  $\varphi$  is effectively a new definition of  $V$ .
- For each block  $X$  and variable  $V$ , there must be at most one  $\varphi$  for  $V$  in  $X$ .

This means that the above iterative process can be done with a single worklist of nodes for each variable  $V$ , initialized to handle all original assignment nodes  $X$  simultaneously.

# Minimal SSA

A program is in SSA form if:

- each variable is assigned a value in **exactly one** statement
- each **use** of a variable is **dominated** by the **definition** i.e., the use can refer to a unique name.

**Minimal SSA:** As few as possible  $\phi$ -functions,

**Pruned SSA:** As few as possible  $\phi$ -functions and no dead  $\phi$ -functions (i.e., the defined variable is used later)

- One needs to compute liveness information
- More precise, but requires additional time

# SSA Construction Algorithm

## Steps:

1. Compute the dominance frontiers\*
2. Insert  $\phi$ -functions
3. Rename the variables

**Thm.** Any program can be put into minimal SSA form using the previous algorithm. [Refer to the paper for proof]

# Dominance in Flow Graphs (review)

Let  $d, d_1, d_2, d_3, n$  be nodes in  $G$ .

$d$  **dominates**  $n$  (“ $d$  dom  $n$ ”) iff every path in  $G$  from  $s$  to  $n$  contains  $d$

$d$  **properly dominates**  $n$  (“ $d$  pdom  $n$ ”) if  $d$  dominates  $n$  and  $d \neq n$

$d$  **is the immediate dominator of**  $n$  (“ $d$  idom  $n$ ”)

if  $d$  is the last proper dominator on any path from initial node to  $n$ ,

**DOM**( $x$ ) denotes the set of dominators of  $x$ ,

**Dominator tree\***: the children of each node  $d$  are the nodes  $n$  such that “ $d$  idom  $n$ ” ( $d$  immediately dominates  $n$ )

# Dominance Frontier

The dominance frontier of node  $X$  is the **set of nodes  $Y$**  such that  **$X$  dominates a predecessor of  $Y$** , but  $X$  does not properly dominate  $Y$  \*

$$\mathbf{DF(X)} = \{Y \mid \exists P \in \text{Pred}(Y) : X \text{ dom } P \text{ and not } (X \text{ pdom } Y)\}$$

**We can split  $\mathbf{DF(X)}$**  in two groups of sets:

$$\mathbf{DF}_{\text{local}}(X) \equiv \{Y \in \text{Succ}(X) \mid \text{not } X \text{ idom } Y\}$$

$$\mathbf{DF}_{\text{up}}(Z) \equiv \{Y \in \mathbf{DF}(Z) \mid \exists W. W \text{ idom } Z \text{ and not } W \text{ pdom } Y\}$$

**Then:**

$$\mathbf{DF(X)} = \mathbf{DF}_{\text{local}}(X) \cup \bigcup_{Z \in \text{Children}(X)} \mathbf{DF}_{\text{up}}(Z)$$

\* **child, parent, ancestor, and descendant** always refer to the dominator tree.  
**predecessor, successor, and path** always refer to CFG

# Dominance Frontier Algorithm

for each  $X$  in a bottom-up traversal of the dominator tree  
(visit the node  $X$  in the tree after visiting its children):

$DF(X) \leftarrow \emptyset$

for each  $Y \in \text{succ}(X)$  */\* local \*/*

if not  $X \text{ idom } Y$  then

$DF(X) \leftarrow DF(X) \cup \{Y\}$

for each  $Z \in \text{children}(X)$  */\* up \*/*

for each  $Y \in DF(Z)$

if not  $X \text{ idom } Y$  then

$DF(X) \leftarrow DF(X) \cup \{Y\}$

00039
```

# SSA Construction Algorithm

## Steps:

1. Compute the dominance frontiers
2. Insert  $\phi$ -functions
3. Rename the variables

# Insert $\varphi$ -functions

for each variable  $V$

HasAlready  $\leftarrow \emptyset$

EverOnWorkList  $\leftarrow \emptyset$

WorkList  $\leftarrow \emptyset$

for each node  $X$  that may modify  $V$

EverOnWorkList  $\leftarrow$  EverOnWorkList  $\cup \{X\}$

WorkList  $\leftarrow$  WorkList  $\cup \{X\}$

# Insert $\phi$ -functions

for each variable  $V$

HasAlready  $\leftarrow \emptyset$

EverOnWorkList  $\leftarrow \emptyset$

WorkList  $\leftarrow \emptyset$

for each node  $X$  that may modify  $V$

EverOnWorkList  $\leftarrow$  EverOnWorkList  $\cup \{X\}$

WorkList  $\leftarrow$  WorkList  $\cup \{X\}$

while WorkList  $\neq \emptyset$

remove  $X$  from WorkList

for each  $Y \in \text{DF}(X)$

if  $Y \notin \text{HasAlready}$  then

insert a  $\phi$ -node for  $V$  at  $Y$

HasAlready  $\leftarrow$  HasAlready  $\cup \{Y\}$

if  $Y \notin \text{EverOnWorkList}$  then

EverOnWorkList  $\leftarrow$  EverOnWorkList  $\cup \{Y\}$

WorkList  $\leftarrow$  WorkList  $\cup \{Y\}$

# Renaming Variables\*

Renaming definitions is easy – just keep the counter for each variable.

To **rename each use** of  $V$  :

(a) **Use in non- $\phi$ -functions**: Refer to immediately dominating definition of  $V$  (+  $\phi$  nodes inserted for  $V$  ).

**preorder on Dominator Tree!**

(b) **Use as a  $\phi$ -function operand**: Refer to the definition that immediately dominates the node with the incoming CFG edge (not the node with the  $\phi$ -function)

**rename the  $\phi$ -operand when processing the predecessor basic block!**

\* For the full algorithm refer to the paper

j=1;

while (j < X)  
    ++j;

N = j;

A: j = 1;

B: if (j >= X) goto E;

S:

j = j+1;

if (j < X) goto S;

E:

N = j;

$j=1;$

while ( $j < X$ )  
     $++j;$

$N = j;$

A:  $j_0 = 1;$

B: if ( $j_0 \geq X$ ) goto E;

S:  $j_1 = \varphi(j_0, j_2)$

$j_2 = j_1 + 1;$

if ( $j_2 < X$ ) goto S;

E:  $j_3 = \varphi(j_0, j_2)$

$N = j_3;$

# Translating Out of SSA Form

## Overview:

1. Dead-code elimination (prune dead  $\phi$ s)
2. Replace  $\phi$ -functions with copies in predecessors
3. Register allocation with copy coalescing

# Control Dependence

**Def.** Postdomination: node  $p$  postdominates a node  $d$  if all paths to the exit node of the graph starting at  $d$  must go through  $p$

**Def.** In a CFG, **node  $Y$  is control-dependent on node  $B$**  if

- There is a non-empty path  $N_0 = B, N_1, N_2, \dots, N_k = Y$  such that  $Y$  postdominates  $N_1 \dots N_k$ , and
- $Y$  does not strictly postdominate  $B$

**Def.** **The Reverse Control Flow Graph (RCFG)** of a CFG has the same nodes as CFG and has edge  $Y \rightarrow X$  if  $X \rightarrow Y$  is an edge in CFG.

- $p$  is a postdominator of  $d$  iff  $p$  dominates  $d$  in the RCFG.

# Computing Control Dependence

**Key observation:** Node  $Y$  is control-dependent on  $B$  *iff*  $B \in DF(Y)$  in RCFG.

## Algorithm:

1. Build RCFG
2. Build dominator tree for RCFG
3. Compute dominance frontiers for RCFG
4. Compute  $CD(B) = \{Y \mid B \in DF(Y)\}$ .

$CD(B)$  gives the nodes that are control-dependent on  $B$ .

# Summary

## Complexity:

The conversion to SSA form is done in three steps:

- (1) The *dominance frontier* mapping is constructed from the control flow graph *CFG* (Section 4.2). Let *CFG* have  $N$  nodes and  $E$  edges. Let  $DF$  be the mapping from nodes to their dominance frontiers. The time to compute the dominator tree and then the dominance frontiers in *CFG* is  $O(E + \sum_x |DF(X)|)$ .
- (2) Using the dominance frontiers, the locations of the  $\phi$ -functions for each variable in the original program are determined (Section 5.1). Let  $A_{tot}$  be the *total* number of assignments to variables in the resulting program, where each ordinary assignment statement  $LHS \leftarrow RHS$  contributes the length of the tuple  $LHS$  to  $A_{tot}$ , and each  $\phi$ -function contributes 1 to  $A_{tot}$ . Placing  $\phi$ -functions contributes  $O(A_{tot} \times avgDF)$  to the overall time, where  $avgDF$  is the weighted average (7) of the sizes  $|DF(X)|$ .
- (3) The variables are renamed (Section 5.2). Let  $M_{tot}$  be the total number of mentions of variables in the resulting program. Renaming contributes  $O(M_{tot})$  to the overall time.

## Follow up works:

- A linear time algorithm for placing phi-nodes (POPL 1995)  
<https://dl.acm.org/citation.cfm?id=199464>
- Algorithms for computing the static single assignment form (JACM 2003)
